Jul 21 2016 Once that happens code will resume execution at the catch

If there is a breakpoint within a function that is evaluated as part of a when that breakpoint will suspend execution before any stack unwinding occurs by contrast a breakpoint at a catch will only suspend execution after all finally handlers have run 22 If there is a hierarchy of exceptions you can use the base class to catch all subclasses of exceptions

In the degenerate case you can catch all Java exceptions with If you re throw an exception within the catch block and that exception is caught inside of another catch block everything executes according to the documentation May 18 2010 Finally and catch blocks are quite different Within the catch block you can respond to the thrown exception

This block is executed only if there is an unhandled exception and the type matches the one or is subclass of the one specified in the catch block's parameter

Finally will be always executed after try and catch blocks whether there is an exception raised or not 19 Cleaner code using async await with Promise catch handler. From what I see this has been a long standing problem that has bugged both meanings many programmers and their code

The Promise .catch is really no different from try catch

ES6 Promise catch handler and work harmoniously with await async providing a proper solution and Oct 21 2013 Try Catch will catch an exception and allow you to handle it and perhaps handling it means to stop execution but it won't do that implicitly

It will actually consume the exception unless you rethrow it Nope or is its friend and always there as part of try catch. However it is perfectly valid to have them empty like in your example

In the comments in your example code If func1 throws error try func2 it would seem that what you really want to do is call the next function inside of the block of the previous Will Try Catch capture all errors that ERROR can? In the following code fragment is it worthwhile to check for ERROR? Will RETURN 1111 ever occur? SET XACT\_ABORT ON BEGIN TRANSACTION BEGIN Catch will only run if an exception is thrown and the catch block can handle that type of exception

The finally block is the one that will run when the try block is complete 37 You don't need to cover every block with try catches because a try catch can still catch unhandled exceptions thrown in functions further down the call stack

So rather than have every function have a try catch you can have one at the top level logic of your application.
