Natural selection is a mechanism of evolution and explains how species adapt to their environment over time through variations in traits

Examples include the peppered moth adapting to industrial pollution yearly flu virus changes and antibiotic resistant bacteria The mechanism that Darwin proposed for evolution is natural selection

Because resources are limited in nature organisms with heritable traits that favor survival and reproduction will tend to leave more offspring than their peers causing the traits to increase in frequency over generations Discover how evolution remains an ongoing process with natural selection and genetic variation driving adaptation

Compare evidence across scales to see how unity and diversity arise from evolutionary change Darwin's theory was based on the mechanism of natural selection which explains how populations can evolve in such a way that they become better suited to their environments over time Mutations simply change the genetic code and can often add variability which may make an organism more or less fit to its environment

Mutations are the source of variation that powers natural selection and evolution. Does that help? Review your understanding of natural selection in this free article aligned to NGSS standards Cmo funciona la selección natural a nivel de genes alelos genotipos y fenotipos Oops. Something went wrong

Please try again. Uh oh it looks like we ran into an error. You need to refresh. If this problem persists tell us Natural selection is the impact of the natural environment on a population of organisms

Over a single or a few generations the effect is going to be small but the effect builds up over many generations into larger changes La selección natural es un proceso que favorece los rasgos heredables que aumentan las posibilidades de supervivencia de un organismo y permiten que el organismo se reproduzca más.
