Sep 22 2010 super is a special use of the `super` keyword where you call a parameterless parent constructor

In general the `super` keyword can be used to call overridden methods access hidden fields or invoke a superclass `s` constructor Feb 23 2009 super lets you avoid referring to the base class explicitly which can be nice

But the main advantage comes with multiple inheritance where all sorts of fun stuff can happen Nov 3 2015 The one without `super` hard codes its parent `s` method thus is has restricted the behavior of its method and subclasses cannot inject functionality in the call chain

The one with `super` has greater flexibility. The call chain for the methods can be intercepted and functionality injected In fact multiple inheritance is the only case where `super` is of any use

I would not recommend using it with classes using linear inheritance where it is just useless overhead I'm currently learning about class inheritance in my Java course and I don't understand when to use the `super` call? Edit I found this example of code where `super` variable is used class A { Jul 23 2009 The automatic insertion of `super` by the compiler allows this

Enforcing `super` to appear first enforces that constructor bodies are executed in the correct order which would be `Object > Parent > Child > ChildOfChild > SoOnSoForth` Dec 18 2024 super object has no attribute `__sklearn_tags__`. This occurs when I invoke the `fit` method on the `RandomizedSearchCV` object

I suspect it could be related to compatibility issues between Scikit learn and XGBoost or Python version. I am using Python 3.12 and both Scikit learn and XGBoost are installed with their latest versions

I attempted to tune the hyperparameters of an `XGBRegressor` As for chaining `super` as I mentioned in the question I have still to find an interesting use to that

For now I only see it as a hack but it was worth mentioning if only for the differences with Java where you can't chain `super` Jul 9 2018 I wrote the following code

When I try to run it as at the end of the file I get this stacktrace
AttributeError super object has no attribute `do_something`
class Parent def `__init__` self
What is the difference between `List<?superT>` and `List<? extends T>`?
I used to use `List<? extends T>` but it does not allow me to add elements to it
`list.add e` whereas the `Li`.
