It meanstail f command will wait for new strings in the file and show these strings dynamically. This command useful for observing log files

For example try tail f var log messages From thetail 1 man page With follow f taildefaults to following the file descriptor which means that even if atailed file is renamed tailwill continue to track its end

This default behavior is not desirable when you really want to track the actual name of the file not the file descrip tor e.g. log rotation. Use follow=name in that case. That causetailto track the Tailwill then listen for changes to that file

If you remove the file and create a new one with the same name the filename will be the same but it s a different inode and probably stored on a different place on your disk .tail f fill not retry and load the new inode tail F will detect this Dec 17 2023 How total f multiple files and grep each file individually in single output? Ask Question Asked 2 years ago Modified 1 year 11 months ago Oct 17 2023 I have to grab the first two lines the lines 43 and 44 and the last 2 lines from a file in one conduct of commands

Is there away to print those while only using head tailand pipe commands AND Say I have a huge text file >2GB and I just want to cat the lines X to Y e.g. 57890000 to 57890010. From what I understand I can do this by piping head intotailor viceversa i.e

head A A simple pipe total n 200 should suffice. Example Sample data. \$ touch \$ seq 300 Now the last 200 \$ ls l tail n 200 You might not like the way the results are presented in that list of 200. For that you can control the order of the results that ls outputs through a variety of switches

For example the data I ve generated is numeric You can use this to strip the first two lines tail n +3 foo.txt and this to strip the last two lines if your implementation of head supports it head n 2 foo.txt assuming the file ends with \n for the latter Feb 20 2024 tail bytes 100M logfile.log tailHowever if you re using GNU Coreutil stailimplementation that already does this i.e

it seeks to the end of the file minus 2.5 kB and looks from there

By not abusing cat here but lettingtailread the file itself or just using redirection works the same! instead you get a much faster result Here is what I know I can do tail n 15 F mylogfile.txt As the log file is filled tailappends the last lines to the display

I am looking for a solution that only displays the last 15 lines and get rid of the lines before the last 15 after it has been updated. Would you have an idea?.
